Echolocation and Sonar

How Dolphins Use Sound
Echolocation Movie

- Why does this person use echolocation?
- What is the range this person is capable of?
- Do you think you could learn to echolocate?

https://www.youtube.com/watch?v=UXh-X1iveU
http://phet.colorado.edu/en/simulation/sound
It’s best if all students have an opportunity to play with the website. Show them, and then have them play with the simulation.
Echo Introduction

- Have you heard an echo before?
- What is an echo?
- What makes an echo?
Echo

- Sound hits an object and bounces back
- You hear the bounce

How scientists know how fast sound travels...
They send out a sound and then wait for it to come back.
The time it takes to come back tells them how far away objects are.
They need to send lots of sounds in very specific directions and then they can tell
not only how far away, but where and how big the objects are.

Bat, Dolphin and Whale Communication

• Watch the video

Watch the video at http://www.dosits.org/audio/interactive/#/50 chose “Audio Gallery”, choose Humpback Whale, scroll down to the video of humpback whales off the coast of Hawaii.

• Is it easier to see or hear the whales?

After watching the video and asking the question, show the video again to ensure everyone understands

You can always hear the whales, but it is difficult to see through the murky water. The sound travels well through the water, but our eyes can’t pick up the images as clearly.
Scientists all agree that dolphins communicate with one another by using sounds and body language.

Types of Dolphins
Dolphins and porpoises are the smallest toothed whales. Bottlenose dolphins, like Flipper the TV star, are the most familiar.

Oceanic Dolphins

- Including orcas and pilot whales, there are 32 species of oceanic dolphins

Photo from http://www.dosits.org/audio/marinemammals/toothedwhales/commondolphin/
River Dolphins

• There are 5 species of river dolphins

Photo from: http://www.dosits.org/audio/marinemammals/toothedwhales/baiji/
There are 6 species of porpoises. All dolphins are porpoises, but orcas and beluga whales are also porpoises. Flipper, a bottle nosed dolphin, is the kind most people think of when they hear the word “dolphin”.

**Dolphin Communication**

- **Clicks** and **whistles** are the two main types of dolphin vocalization.
- Each dolphin has its own “signature whistle”
- Dolphins recognize each others’ whistles

Signature Whistle: This is a series of whistles (like a dolphin Morse code) distinct from any other member of the group.
Compare this to how we recognize different people’s voices

Echolocation refers to an ability that enables bats, dolphins, and whales to essentially "see" with their ears by listening for echoes. They echolocate by producing clicking sounds and then receiving and interpreting the resulting echo. Dolphins produce directional clicks in trains. Each click lasts about 50 to 128 microseconds.

SONAR is just human echolocation
Animals That Use Echolocation

Dolphin’s Echolocation

- Sound waves travel 4 times faster through water—much faster than sound travels through air!
- These sound waves bounce off objects in the water and return to the dolphin in the form of an echo.
- This is similar to the sound simulation and how the sounds hit the barrier and bounce back.
You may need to play this video more than once. Help students understand that the clicks get faster as the whale gets closer (to narrow location) and the whale can clearly see, but he also using echolocation in addition. (Notes: The video camera is on the bottom of the fishing line looking up. The whale isn’t stuck, he’s just holding on with his teeth.)
Click Trains
The click trains pass through the melon (the rounded region of a dolphin's forehead), which consists of lipids (fats). The melon acts as an acoustical lens to focus these sound waves into a beam, which is projected forward into water in front of the animal.

Detailed Information
The major areas of sound reception are the fat-filled cavities of the lower jaw bones. Sounds are received and conducted through the lower jaw to the middle ear, inner ear, and then to hearing centers in the brain via the auditory nerve.

The brain receives the sound waves in the form of nerve impulses, which relay the messages of sound and enable the dolphin to interpret the sound's meaning.

By this complex system of echolocation, dolphins and whales can determine size, shape, speed, distance, direction, and even some of the internal structure of objects in the water.

Bottlenose dolphins are able to learn and later recognize the echo signatures returned by preferred prey species.
High frequency sounds don't travel far in water. Low frequency sounds travel farther because of their longer wavelength and greater energy. Echolocation is most effective at close to intermediate range because dolphins and whales use high frequency sounds. Their range is about 5-200 meters for targets 5-15 centimeters in length. This would be like clearly identifying a banana from 2 football fields away.

Despite the effectiveness of echolocation, studies show that a visually-deprived dolphin takes more time to echolocate on an object than a dolphin using vision in tandem (at the same time) with echolocation.

Common Dolphin Sound Clips

- What did you hear in each sound clip?
- How are the two sounds different from each other?

http://www.dosits.org/audio/marinemammals/toothedwhales/commondolphin/
Go to the audio gallery again and choose “common dolphin” this time and listen to the two sound clips of the dolphins.
Dolphins produce non-verbal sounds by slapping a body part against the surface of the water, which makes both a sound and a splash. Tail or fluke slapping is also common. Kerplunks are another non-vocal sound made by the tail. Other parts of the body used to produce noise in a slapping manner are pectoral fins and the whole body. Finally, jaw claps are made either above or underwater.
